# Stock Prediction System

Renjie Zhang October 18, 2017

# 1 Revision History

| Date       | Version | Notes  |
|------------|---------|--------|
| 2017-09-25 | 1.0     | create |
| 2017-10-04 | 1.1     | update |

## 2 Reference Material

This section records information for easy reference.

### 2.1 Table of Units

| symbol | unit     | SI     |
|--------|----------|--------|
| \$     | currency | dollar |

## 2.2 Table of Symbols

| symbol   | unit       | description  |
|----------|------------|--|
| K        | 1          | The Kernel use to solve the non-linear classification                          |
| y        | integer    | can be 1 or -1, use to represent the result. 1 means increase, -1 is decrease. |
| $\sigma$ | percentage | Stock Price Volality (see 5.2.4 for detail)                                    |
| C        | price      | stock daily price  |

## 2.3 Abbreviations and Acronyms

| symbol                  | description                         |
|-------------------------|-------------------------------------|
| A                       | Assumption                          |
| DD                      | Data Definition                     |
| GD                      | General Definition                  |
| GS                      | Goal Statement                      |
| IM                      | Instance Model                      |
| LC                      | Likely Change                       |
| PS                      | Physical System Description         |
| R                       | Requirement                         |
| SRS                     | Software Requirements Specification |
| Stock Prediction System | Stock Prediction System             |

### 3 Introduction

Stock price prediction is a popular and challenging topic nowadays. There were serveral [spell check!—SS] prediction models such as linear statistical time series models. With the development of Big Data and Machine learning, the prediction technology may have a significant improvement. This project will introduce a stock prediction system is used to analyze the future trend of stocks. The prediction was provided by machine learning algorithms based on the historical data. The system will be run on a big data platform (Spark), in order to obtain the more accurate results. In this case, we need to setup a distributed system to support Spark.

[The text is better for version control, and for reading in other editors, if you use a hard-wrap at 80 characters —SS]

#### 3.1 Purpose of Document

The purpose of this document is to explain how to implement a machine learning system for stock price prediction. With different algorithms and dataset, the system can be used for both short term and long term predictions. In this case, we will use Support Vector Machine to predict the future trend of stocks based on the daily historical data.

### 3.2 Scope of Requirements

The purpose of this software is to give the user a reference by calculating the possibility of the future price change. For example, it may go up with a chance of xx percent and go down with a chance of xx percent.

#### 3.3 Characteristics of Intended Reader

Reader are not required to have any specific background knowledge. However, it is very helpful to have some basic knowledge of big data, machine learning, especially Support Vector Machine. [For the characteristics of intended readers for this optional knowledge try to be more specific about the education. What degree? What course areas? What level?

—SS] [Don't you think the reader should know something about the stock market? —SS]

### 3.4 Organization of Document

This document will cover the configuration of the Spark distributed system for big data, the workflow of the program and the explaination [spell check! —SS] of SVM algorithm. [You should mention the source of the template Smith and Lai (2005); Smith et al. (2007). —SS]

### 4 General System Description

The project have an interface to let the user choose the company, but on the demo there will be only one company to display. It loads the historical data provided by the user and caculate [spell check! —SS] the future trend. A plot graph will be displayed as well. There will be two results come out, one is the possibility of increase and the other is of decrease. [Is this project the demo you are talking about? It is better if your SRS is for the full project and you add a section at the end of the document to explain how the project will be developed starting with a version where the user cannot select the company. —SS]

### 4.1 System Context

- User Responsibilities:
  - Prepare the historical data file [Do you say the contents of this file somewhere in your SRS? The format doesn't matter (that is a design decision for later), but the contents should be specified. —SS]
  - Decide the date time range of the historical period
  - Update the historical data set
- Stock Prediction System Responsibilities:
  - Load data from files and display errors when the loading failes
  - Display the plot of the stock
  - Predict the future trent [trend —SS] based on the historical data with the possibilities

#### 4.2 User Characteristics

The end user of Stock Prediction System should have some basic knowledge of machine learning algorithm (Support Vector Machine).

### 4.3 System Constraints

The system supports multiple operating systems. However, since it is running on Spark, it is more stable with Linux/Ubuntu. The program needs a distributed system consist of at lease three computers, one will be the driver of Spark, the others will be the workers.

### 5 Specific System Description

This system is used to predict the future trend of stocks based on the historical data from Yahoo Finance using Support Vector Machine algorithm. The data from other resource is

acceabled [spell check! —SS] if they fit the format. The programming language will be Python. [Requirements documentation should be abstract. There is no reason to specify the programming language at this time. —SS]

#### 5.1 Problem Description

Stock Prediction is a very important topic in financial industry. It is complicated because the stock price was affected by too many factors. One of the common prediction technology is to train and test the historical data using machin [spell check! —SS] learning. Stock Prediction System is a tool to predict stocks based on machine learning and big data. It implements SVM classifier to train and test the historical data. With the development of Big Data and Machine learning, it is possible to obtain an more accurate prediction result. To delivery a more accurate result, a large scale of data is needed. In this case it is nessary [spell check! —SS] to run the program on a distributed system platform such as Spark to accerate [spell check! —SS] the caculation [spell check! - and elsewhere —SS] speed.

#### 5.1.1 Terminology and Definitions

This subsection provides a list of terms that are used in the subsequent sections and their meaning, with the purpose of reducing ambiguity and making it easier to correctly understand the requirements:

- Support Vector Machine: A supervised learning model with associated learning algorithms that analyze data used for classification and regression analysis. [Some citations would be helpful. —SS]
- Spark: A big data platform that save and retrive data from different machines in a format called RDD(Resilient Distributed Datasets). It provides a set of machine learning libraries and support different types of programming lanauges.
- RDD: Resilient Distributed Datasets (RDD) is a fundamental data structure of Spark. It is an immutable distributed collection of objects. Each dataset in RDD is divided into logical partitions, which may be computed on different nodes of the cluster.
- Distributed System: A distributed system is a model in which components located on networked computers communicate and coordinate their actions by passing messages. It combines a set of computers to work on a single task as one machine.
- Training and Testing: A training set is a set of data used to discover potentially predictive relationships. A test set is a set of data used to assess the strength and utility of a predictive relationship. Test and training sets are used in intelligent systems, machine learning, genetic programming and statistics.

#### 5.1.2 Physical System Description

The physical system of Stock Prediction System, is a distributed system consists by a driver and 2-3 works as shown in Figure ?, [Reference the figure using the ref command, like Figure 1—SS] includes the following elements:

- Driver (Master): The drive is the machine that send requests to the works and receive the response from, it some times called Master. Data will be converted into RDD format and equally assigned to each work. Drive itself does not do the actual works and there is only on drive in the distributed system.
- Worker (Slave): The workers are the machines which do the actual jobs and they are called slaves as well. They receive data from drive using RDD and return an RDD back to drive after certain processes. For each distributed system, there are at least 2 workers, otherwise it will work as a single node computers. Each worker has a copy of the program.

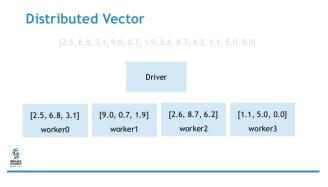

Figure 1

#### 5.1.3 Goal Statements

• Predicture Result1: A result of the future stock price with its probability. [What is the input? Is it just predicting one price, or a sequence of price with probabilities? —SS]

### 5.2 Solution Characteristics Specification

The instance models that govern Stock Prediction System are presented in Subsection 5.2.5. The information to understand the meaning of the instance models and their derivation is also presented, so that the instance models can be verified.

#### 5.2.1 Assumptions

This section simplifies the original problem and helps in developing the theoretical model by filling in the missing information for the physical system. The numbers given in the square brackets refer to the theoretical model [T], general definition [GD], data definition [DD], instance model [IM], or likely change [LC], in which the respective assumption is used.

- A1: Efficient Markets Hypothesis holds true. It posits that stock prices already reflected all available information and are there fore unpredictable.
- A2: Independent identically distributed. A sequence or other collection of random variables is independent and identically distributed (i.i.d. or iid or IID) if each random variable has the same probability distribution as the others and all are mutually independent.
- A3: All companies are active on NASDAQ during the period of 2003-2012. [Why this date? Why is this coming up as an assumption? —SS]
- A4: The historical data is daily.

#### 5.2.2 Theoretical Models

This section focuses on the general equations and laws that Stock Prediction System is based on.

| Number      | T1  |
|-------------|---|
| Label       | Support Vector Machine  |
| Equation    | $y = \beta_0 + \sum a_i y_i K(x(i), x)$   |
| Description | The above equation gives a linear classification in a higher dimensional space and linearly classify in that space. $x$ is an n-dimensional feature vector $x = (X_1,X_n)$ . $y \in \{1, -1\}$ is the label, in a range of 1 and -1. This SVM replaces the inner product with a more general kernel function K which allows the input to be mapped to higher-dimensions. In this case, RBF Kernel is used for price forcasting. [Not all of the symbols are defined. The meaning of RBF is not given. The range of summation indices is not given. —SS] |
| Source      | https://www.cs.princeton.edu/sites/default/files/uploads/saahil_madge.pdf   |
| Ref. By     | DD1 [DD1 does not actually reference T1. —SS]   |

| Number      | T2  |
|-------------|---|
| Label       | Specific Kernel Function  |
| Equation    | $k(X_i, X_k) = \exp\left(-\frac{1}{\delta^2} \sum_{n=1}^{j=1} (X_{ij} - X_{kj})^2\right) \text{ [Wasn't this capital } K \text{ earlier?}$ —SS]   |
| Description | Where delta is known as the bandwidth of the kernel function [You should define all of the symbols here so that T2 is completely documented. —SS] |
| Source      | https://www.cs.princeton.edu/sites/default/files/uploads/saahil_madge.pdf   |
| Ref. By     | DD1   |

#### 5.2.3 General Definitions

There is no General Definitions applied on this project.

#### 5.2.4 Data Definitions

This section collects and defines all the data needed to build the instance models. The dimension of each quantity is also given.

| Number      | DD1  |
|-------------|--|
| Label       | Stock Price Volatility   |
| Symbol      | $\sigma_s$   |
| SI Units    | % percentage [percentage isn't a unit —SS]   |
| Equation    | $\frac{\sum_{i=t-n+1}^{t} \frac{C_i - C_{i-1}}{C_{i-1}}}{n}$   |
| Description | Stock price is an average over the past $n$ days of percent change in the given stocks price per day |
| Sources     | https://www.cs.princeton.edu/sites/default/files/uploads/saahil_madge.pdf                            |
| Ref. By     | IM <mark>1</mark>  |

| Number      | DD2  |
|-------------|--|
| Label       | Stock Momentum   |
| Symbol      | NA   |
| SI Units    | \$ price   |
| Equation    | $\frac{\sum_{i=t-n+1}^t y}{n}$   |
| Description | This is an average of the given stocks momentum over the past $n$ days. Each day is labeled 1 if closing price that day is higher than the day before, and -1 [I had to modify the minus sign so that the correct symbol would show up in the generated pdf file. —SS] if the price is lower than the day before |
| Sources     | https://www.cs.princeton.edu/sites/default/files/uploads/saahil_madge.pdf  |
| Ref. By     | IM <mark>1</mark>  |

| Number      | DD3   |
|-------------|---|
| Label       | Index Volatility  |
| Symbol      | $\sigma_i$  |
| SI Units    | % percentage  |
| Equation    | $\frac{\sum_{i=t-n+1}^{t} \frac{I_i - I_{i-1}}{I_{i-1}}}{n}$                            |
| Description | This is an average over the past $n$ days of percent change in the index's price perday |
| Sources     | https://www.cs.princeton.edu/sites/default/files/uploads/saahil_madge.pdf               |
| Ref. By     | IM <mark>1</mark>   |

| Number      | DD4  |
|-------------|--|
| Label       | Index Momentum   |
| Symbol      | NA   |
| SI Units    | \$ price   |
| Equation    | $\frac{\sum_{i=t-n+1}^{t} d}{n}$   |
| Description | This is an average of the indexs momentum over the past n days. Each day is labeled 1 if closing price that day is higher than the day before, and 1 if the price is lower than the day before |
| Sources     | https://www.cs.princeton.edu/sites/default/files/uploads/saahil_madge.pdf  |
| Ref. By     | IM <mark>1</mark>  |

#### 5.2.5 Instance Models

This section transforms the problem defined in Section 5.1 into one which is expressed in mathematical terms. It uses concrete symbols defined in Section 5.2.4 to replace the abstract symbols in the models identified in Sections 5.2.2 and 5.2.3.

| Number      | IM1   |
|-------------|---|
| Label       | Predict future trend by historical data   |
| Input       | $C_i$ the adjClose, the Date, the format of the input shown as the figure 2   |
| Output      | 1 or -1, the prediction result  |
| Description | Date is the the date of the trade adjClose stands for the adjusted closing price. It is a stock's closing price on any give day of trading that has been amended to include any distributions and corporate actions that occurred at any time prior to the next day's open.  The result of 1 stands for increase and -1 means decrease. |

Figure 2

#### 2. Please be consistent in your capitalization. —SS]

[It is unclear how IM1 relates to the data definitions or theoretical models. A probability is mentioned, but I don't see it in the IM?—SS]

#### 5.2.6 Data Constraints

Tables 1 and 3 show the data constraints on the input and output variables, respectively. The column for physical constraints gives the physical limitations on the range of values that can be taken by the variable. The column for software constraints restricts the range of inputs to reasonable values. The constraints are conservative, to give the user of the model the flexibility to experiment with unusual situations. The column of typical values is intended to provide a feel for a common scenario. The uncertainty column provides an estimate of the confidence with which the physical quantities can be measured. This information would be part of the input if one were performing an uncertainty quantification exercise.

The specification parameters in Table 1 are listed in Table 2.

Table 1: Input Variables

| Var | Physical Constraints | Software Constraints | Typical Value | Uncertainty |
|-----|----------------------|----------------------|---------------|-------------|
| C   | C > 0                | C > 0                | \$1000        | NA          |

(\*)

Table 2: Specification Parameter Values

Table 3: Output Variables

| Var | Physical Constraints |
|-----|----------------------|
| y   | 1 or −1              |

#### 5.2.7 Properties of a Correct Solution

A correct solution must exhibit. The solution is two results, 1 and -1, each result is with a percentage number. Any other outputs are incorrect. The result of 1 means the stock is increase, otherwise decreasing.

### 6 Requirements

The required functions are not complex in the system. It basicly reads a data file and analysis the data then out put a result based on the analysis.

#### 6.1 Functional Requirements

- R1: The system must read the input data file provided by the user successfully. This is the first and every other functions rely on it. If the loading has any errors then the whole system will not work.
- R2: As part of the interface and output, the system needs to generate a graph that explains the historical data. The graph is a plot consists by the points of stock price and date.
- R3: The system needs to calculate the future trend of the stock by training and testing the historical data and finally obtained an acurte result. This is the most important function and it is also the core of the system.
- R4: The input reading and data calculating must be valid and verified. Invalid data must be skipped and the data type and format must match
- R5: There will be an result about the prediction. The result shows the stock will go up or go down with a probability in a percentage format.

[Functional requirements should reference the instance models. —SS]

### 6.2 Nonfunctional Requirements

The system needs to have a more friendly interface and the layout of the plot graph. [More information on the NFRs would improve this document. —SS]

### 7 Likely Changes

LC1: In short run, we may need intra-day/high frequency data to increase the accuracy.

LC2: Try to get more data with longer history and with a larger size of distributed system.

### 8 Traceability Matrices and Graphs

The purpose of the traceability matrices is to provide easy references on what has to be additionally modified if a certain component is changed. Every time a component is changed, the items in the column of that component that are marked with an "X" may have to be modified as well. Table 4 shows the dependencies of theoretical models, general definitions, data definitions, and instance models with each other. Table 5 shows the dependencies of instance models, requirements, and data constraints on each other. Table 6 shows the dependencies of theoretical models, general definitions, data definitions, instance models, and likely changes on the assumptions.

|        | T1 | T2 | DD1 | DD2 | DD3 | DD4 | IM <mark>1</mark> |
|--------|----|----|-----|-----|-----|-----|-------------------|
